Patent Office
Canberra

I, LEANNE MYNOTT, TEAM LEADER EXAMINATION SUPPORT AND SALES hereby certify that annexed is a true copy of the Provisional specification in connection with Application No. PQ 0203 for a patent by STEM CELL SCIENCES PTY LTD filed on 06 May 1999.

WITNESS my hand this
Nineteenth day of May 2000

LEANNE MYNOTT
TEAM LEADER EXAMINATION
SUPPORT AND SALES

**PRIORITY
DOCUMENT**
SUBMITTED OR TRANSMITTED IN
COMPLIANCE WITH RULE 17.1(a) OR (b)

AUSTRALIA

Patents Act 1990

PROVISIONAL SPECIFICATION

Invention Title: **Nuclear addition**

The invention is described in the following statement:

NUCLEAR ADDITION

This invention relates to the generation of cells, embryos and animals by nuclear addition, including but not limited to the generation of cloned and transgenic animals.

5 Nuclear transfer is the replacement of the nucleus of one cell with that of another. The ability to produce live offspring by nuclear transfer is an objective which has been sought for some time by animal breeders. The ability to produce cloned offspring in such a manner would enable the production of large numbers of identical offspring and the ability to genetically modify and/or select cell
10 populations of the required genotype (e.g. sex or transgenic) prior to embryo reconstruction.

 Whilst nuclear transfer has been described in some animals, the procedures used are often inefficient and have not yet been successfully applied to many species.

15 It is an object of the present invention to overcome, or at least alleviate, one or more of the difficulties or deficiencies associated with the prior art.

 In a first aspect of the present invention, there is provided a method of preparing an anuploid cell which method includes

 providing
20 a donor nucleus, and
 a recipient cell; and
 adding the donor nucleus to the recipient cell to produce an anuploid cell.

 In a second aspect of the present invention there is provided a method of
25 generating an animal embryo which method includes

 providing
 a donor nucleus, and
 a recipient cell;

adding the donor nucleus into the recipient cell to produce an anuploid cell;
and
generating an animal embryo from the anuploid cell.

Accordingly, the method of the present invention involves nuclear addition,
5 ie. the addition of the nucleus of one cell to another cell.

Whilst Applicant does not wish to be restricted by theory, it is postulated
that the donor nucleus forms the animal embryo and an anuploid (eg 3N) placenta
may be formed. This may provide advantages over normal duploid placentas.
For example, the anuploid placenta may be bigger and more vigorous, which may
10 in turn improve embryo viability. Alternatively the nucleus of the recipient cell may
be expelled from the cell and participate no further in the development of the
embryo.

The process of the present invention may include the further step of
generating an animal from the animal embryo.

15 In a further aspect of the present invention there is provided a method of
preparing a genetically modified anuploid cell, said method including
providing
a donor nucleus which has been genetically modified to eliminate or
reduce an undesirable activity or to provide for or increase a desirable
20 activity, and
a recipient cell; and
transferring the donor nucleus to the recipient cell to produce the
genetically modified anuploid cell.

In a still further aspect of the present invention there is provided a method
25 of generating a transgenic animal embryo said method including
providing
a donor nucleus which has been genetically modified to eliminate or
reduce an undesirable activity or to provide for or increase a desirable
activity, and

a recipient cell;

adding the donor nucleus to the recipient cell to produce a genetically modified anuploid cell; and

generating a transgenic animal embryo from said anuploid cell.

5 In an alternate form of this aspect of the invention, the method may include the further step of

removing the DNA of the recipient cell, preferably prior to division of the anuploid cell.

Removal of the DNA of the recipient cell may be performed, for example,
10 approximately 1 to 20, more preferably approximately 3 to 12, most preferably approximately 6 to 8 hours after completion of the nuclear addition procedure.

In a preferred form of this aspect of the invention the method may include the further step of maintaining the anuploid cell in a suitable medium for a period sufficient to allow the cell to recover a substantially normal shape.

15 Applicant has discovered that the number of viable embryos produced may be significantly increased by permitting the reconstituted cell to be maintained in a quiescent state for a period sufficient to allow the cell to recover a substantially normal, e.g. generally circular, shape.

Whilst applicant does not wish to be restricted by theory, it is postulated
20 that the quiescent period permits the cell to return to a more normal state after which cell fusion may proceed more efficiently.

The reconstituted cell may be maintained in a suitable medium preferably for a period of approximately 3 to 8 hours, more preferably approximately 4.5 to 6 hours.

25 It is desirable, however, that the quiescent period end before any, or any substantive division, ensues.

In a preferred embodiment of the present invention, the method may include the preliminary step of
subjecting the recipient cell to an activation step.

Activation occurs during fertilisation when the penetrating sperm triggers
5 the resumption of meiosis. Activation is characterised by calcium oscillation, release of cortical granules, extrusion of the second polar body, pronuclear formation and ultimately cleavage. The anuploid cell may be treated with, but not limited to, for example, ethanol, calcium ionophore or electrical stimulation to induce activation. Activation is preferably performed prior to the addition of the
10 donor nuclei.

Applicants have found, in this preferred embodiment, improved results where a preliminary activation step is undertaken.

Preferably the anuploid cell is subsequently subjected to cell fusion.

Where the preferred preliminary activation step is not utilised the anuploid
15 cell may be subjected to a cell fusion/activation step. For example, where electrical pulses are utilised for cell fusion, the voltage may be selected to simultaneously initiate activation.

The anuploid cell may be also be subjected to simultaneous cell fusion/activation or a process of cell fusion followed later by activation.

20 The method according to this aspect of the present invention may include the further step of generating a transgenic animal from the transgenic animal embryo.

The donor nucleus may be of any suitable type and from any suitable species. The donor nucleus may be contained in a karyoplast or cell. The donor
25 nucleus may be of embryonic, embryonal tumor, foetal or adult origin. Donor nuclei may be prepared by removing the nucleus and a portion of the cytoplasm and plasma membrane surrounding it from early pre-implantation stage embryos

(for example zygotes, 4- to 16- cell embryos) for example using microsurgery. When nuclei from more advanced embryonic cells are used the whole blastomere may be transferred to the recipient cytoplasm. Embryonic or foetal fibroblasts may be used. Embryonic stem (ES) cells [isolated from inner cell mass (ICM) cells, 5 embryonic disc (ED) cells or primordial germ cells (PGC)] may be used. A cell line derived from an embryonal tumor may be used (eg. embryonal carcinoma (EC) or yolk sac tumor cells). Adult cells such as fibroblasts may also be used. In this case the whole cell may be fused to the recipient cytoplasm.

10 It is particularly preferred that the donor cells be at a particular stage in the cell cycle, for example G₀, G₁ or Sphase. Applicant has found that it is possible to isolate populations of cells which are enriched for cells at each stage in the cell cycle by sorting the cells on the basis of size, for example using FACS. This avoids the use of stains, which are toxic to the cells. Staining can be used on a sample of each size-sorted population to identify what stage in the cell cycle that 15 population is at.

The recipient cell may be of any suitable type and from any suitable species. Recipient cells may be *in vivo* or *in vitro* produced oocytes. Recipient cells may be oocytes, for example arrested in the second metaphase of meiotic maturation (MII oocytes). Other sources of recipient cells include zygotes, fertilised 20 oocytes, 2-cell blastomeres, cell lines produced from gonads, or any cell type suitable for allowing the successful addition of a nucleus.

The donor nucleus may be transferred to the recipient cell by any suitable method. Such methods include, but are not limited to, microsurgical injection, and cell fusion for example mediated by electrical pulses (electrofusion), chemical 25 reagents such as polyethyleneglycol or the use of inactivated virus such as Sendai virus.

Preferably the donor nucleus for addition is introduced under the zona pellucida.

Optional removal of the DNA from the recipient cell may be performed by

any suitable technique. The DNA may be removed by microsurgery. Alternatively, nonphysical approaches such as inactivation of the chromosome by UV, chemicals or laser irradiation may be used.

5 An animal embryo may be generated from the anuploid cell by any suitable method. Embryonic development may be initially *in vitro* and subsequently in a surrogate. Thus, the reconstituted cell may be initially cultured *in vitro* to produce an embryo and then the embryo may be transferred to a surrogate for subsequent development into an animal. *In vitro* culture of the anuploid cells may be in any suitable medium.

10 The animal embryo or animal may be of any type, and includes bird, fish, reptile and mammalian (including ungulate and primate) embryos including human embryos, e.g. murine, bovine, ovine or porcine embryos. Preferably, the animal embryo is a porcine embryo, bovine embryo, sheep embryo, murine embryo or human embryo.

15 In a preferred embodiment of this aspect of the present invention, the donor nucleus for addition may be from an embryo that is itself the product of nuclear transfer or nuclear addition. This could be called serial nuclear transfer and/or addition.

20 Serial nuclear transfer and/or addition may improve the capacity of differentiated nuclei to direct normal development. Whilst applicant does not wish to be restricted by theory, serial nuclear transfer and/or addition is postulated to improve the developmental capacity of transplanted nuclei by allowing specific molecular components in the oocyte to assist in chromatin remodelling that is essential for nuclear reprogramming. Serial nuclear transfer and/or addition is not
25 restricted to a singular event but may be initiated on more than one occasion to sequentially improve conditions for chromatin remodelling, nuclear reprogramming and embryonic development

The donor nucleus for addition and recipient cell which are used in the method of the present invention may be of any suitable origin. Preferably, they are

of porcine, bovine, ovine, rodent, avian, fish, reptile, murine or human origin.

The method of the present invention may be used to generate transgenic animals. For example, a new gene may be expressed and/or an existing gene may be deleted in the transgenic animal. The addition of new genes is technically
5 less demanding than the deletion of existing genes.

As used in this specification the term "transgenic", in relation to animals and all other species, should not be taken to be limited to referring to animals containing in their germ line one or more genes from another species, although many transgenic animals will contain such a gene or genes. Rather, the term
10 refers more broadly to any animal whose germ line has been the subject of prior technical intervention by recombinant DNA technology particularly nuclear addition. So, for example, an animal in whose germ line an endogenous gene has been deleted or modified (either by modifying the gene product or pattern of expression) is a transgenic animal for the purposes of this invention, as much as
15 an animal to whose germ line an exogenous nucleic acid sequence has been added.

The donor nucleus used for nuclear addition may be genetically modified by modifying, deleting or adding one or more genes. The gene(s) to be modified, deleted or added may be of any suitable type.

20 The process of modifying a gene may involve the introduction of one or more mutations in both copies of the target gene. Suitable cells may take up the mutation(s) and then be used to generate an animal. One copy of the gene may be disrupted in the cell and the resultant heterozygous animals bred with each other until one with both copies of the gene mutated is found. Alternatively, both
25 copies of the gene may be modified *in vitro*.

To target an endogenous gene rather than introduce random mutations, a DNA construct (transgene) including a nucleic acid sequence which is substantially isogenic to at least one or more portions of the target gene except for the introduction of the one or more mutations may, be used.

The targeting DNA may comprise a sequence in which the desired sequence modification is flanked by a substantially isogenic DNA and a corresponding target sequence in the genome to be modified. The substantially isogenic sequence is preferably at least about 97-98% identical with the corresponding target sequence (except for the desired sequence modifications), more preferably at least about 99.0-99.5% identical, most preferably about 99.6% to 99.9% identical. The targeting DNA and the target DNA preferably share stretches of DNA at least about 75 base pairs that are perfectly identical, more preferably at least about 150 base pairs that are perfectly identical, even more preferably at least about 500 base pairs that are perfectly identical. Accordingly, it is preferable to use targeting DNA derived from cells as closely related as possible to the cell being targeted; more preferably, the targeting DNA is derived from cells of the same haplotype as the cells being targeted. Most preferably, the targeting DNA is derived from cells of the same individual (or animal) as the cells being targeted. Preferably, the targeting DNA sequence comprises at least about 100-200 base pairs of substantially isogenic DNA, more preferably at least about 300-1000 base pairs of substantially isogenic DNA, even more preferably at least 1000-15000 base pairs of substantially isogenic DNA.

As used herein, the term isogenic or substantially isogenic DNA refers to DNA having a sequence that is identical with or nearly identical with a reference DNA sequence. Indication that two sequences are isogenic is that they will hybridise with each other under the most stringent hybridisation conditions (see e.g., Sambrook, J., Fritsch, E.F., Maniatis, T., (1989) *Molecular Cloning - A Laboratory Manual*, Cold Spring Harbour Laboratory Press, New York); and will not exhibit sequence polymorphism (i.e. they will not have different sites for cleavage by restriction endonucleases). The term "substantially isogenic" refers to DNA that is at least about 97-99% identical with the reference DNA sequence, and preferably at least about 99.5-99.9% identical with the reference DNA sequence and in certain cases 100% identical with the reference DNA sequence. Indications that two sequences are substantially isogenic is that they will still hybridise with each other under the most stringent conditions (see Sambrook, J., et al., 1989) and that they will only rarely exhibit restriction fragment length polymorphism

(RFLP) or sequence polymorphism (relative to the number that would be statistically expected for sequences of their particular length which share at least about 97-98% sequence identity). In general, a targeting DNA sequence and a host cell sequence are compared over a window of at least about 75 consecutive nucleotides. DNA sequences compared between individuals of a highly inbred strain, such as the MHC inbred miniswine, are generally considered to be substantially isogenic even if detailed DNA sequence information is not available, if the sequence do not exhibit sequence polymorphisms by RFLP analysis.

Thus, the donor nucleus for addition may be genetically modified by modifying an endogenous gene in the donor nucleus. The endogenous gene may be modified by introducing into said donor nucleus a DNA construct including a nucleic acid sequence which is substantially isogenic to at least one or more portions of the endogenous gene and includes one or more mutations, such that there is homologous recombination between the DNA construct and the endogenous gene.

The introduction of new genetic material and the subsequent selection of cells harbouring the desired targeted integration requires expansion and clonal selection of each founder transgenic cell. A limitation to applying this process in nuclear transplantation programs is the number of cell divisions which the transfected cell must undergo to provide sufficient material for molecular analysis of each transgenic colony and subsequent supply of nuclei for transfer. The great majority of cells suitable for *in vitro* genetic modification and subsequent nuclear transfer have limited *in vitro* propagation capacity. It is therefore desirable to utilise transfection and selection systems which generate and/or identify correctly targeted clones at high efficiency and with limited requirement for *in vitro* propagation.

A particularly efficient approach to selecting for correctly targeted clones is to use IRES gene trap targeting vectors, as described in Australian Patent 678234, the entire disclosure of which is incorporated herein by reference. The IRES gene trap targeting vector may be selected from IRES-neo, IRES-lacZ, (TAA₃) IRES-lacZ, (TAA₃) IRES-lacZ lox neo-tk lox, (TAG₃) IRES-lacZ/mcIneo, SA

lacZ-IRES neo, SA (TAA₃) IRES-nuclear lacZ, SA (TAA₃) IRES-nuclear lacZ lox
 Gpt neo, IRES-βgeo, (TAA₃) IRES-βgeo, SA IRES-βgeo, SA Optimised IRES-β-
 geo, IRES-nuclear βgeo, SA IRES-nuclear βgeo, SA (TAA₃) IRES-nuclear βgeo,
 SA Optimised IRES-nuclear βgeo, IRES-zeo, SA IRES-zeo, IRES-hph, SA
 5 IRES-hph, IRES-hph-tk, IRES-bsd, SA IRES-bsd, IRES-puro. IRES gene trap
 targeting vectors provide a significant enhancement in gene targeting efficiency by
 eliminating a large proportion of random integration events. IRES gene trap
 targeting vectors rely upon functional integration into an actively transcribed gene
 (such as the target gene) for expression of the selectable marker. Random
 10 integrations into non-transcribed regions of the genome are not selected.

In a preferred embodiment, it may be desirable to remove the selectable
 marker cassette from the targeted locus to eliminate expression of the eg.
 antibiotic resistance gene. One approach is to flank the IRES selectable marker
 cassette with suitable DNA sequences which act as recombination sites following
 15 the addition of a suitable site-specific recombinase. One example of a suitable
 recombinase site is the lox site which is specific for the Cre recombinase protein.
 Another example of a suitable recombinase is the FLP/FRT recombinase system
 (O'Gorman, S., Fox, D.T., Wahl, G.M. (1991) Recombinase-mediated gene
 activation and site-specific integration in mammalian cells. *Science* 251(4999),
 20 1351-5).

High efficiency gene targeting and selection has a significant advantage in
 that suitably stringent selection systems, such as the IRES gene trap targeting
 vectors, can eliminate the need for biochemical analysis of clonal cell lines. In this
 instance, individual nuclei from a pool of uncharacterised transgenic cells should
 25 generate offspring of the desired phenotype at a ratio equivalent to the selected
 pool. The elimination of clonal selection may be particularly useful where only
 limited *in vitro* propagation is desirable or possible. One such instance includes
 the culture of embryonic nuclei for nuclear transfer. Embryonic nuclei are more
 efficient than latter stage somatic cells for generating live born offspring by nuclear
 30 transfer. However, totipotent embryonic cells can not be cultured for extended
 periods for any other species than mice. Nuclear recycling of embryonic nuclei

provides an opportunity to maintain, expand and genetically manipulate multipotential cells from animals *in vitro*.

The DNA constructs may be engineered in bacteria and then introduced into the cells. The transgenes may be introduced into the cells by any suitable method. Preferred methods include direct injection, electroporation, liposomes or calcium phosphate precipitation. Direct injection is the preferred method for embryonic cells while electroporation is more suitable for embryonic fibroblast and embryonic stem cell cultures.

Whilst applicant does not wish to be restricted by theory, it is thought that regions of substantially isogenic DNA either side of the mutation drag the transgene to the target site where it recombines and introduces the mutation. It is further thought that the main contributing factor for increasing the efficiency of introducing a specific mutation in a given gene is the degree of similarity between the target DNA and the introduced DNA. Thus, it is preferred that the DNA is isogenic (genetically identical) not allogenic (genetically dissimilar) at the genetic locus that is to be targeted.

In a further aspect of the present invention there is provided an anuploid animal cell or modified anuploid animal cell produced by the methods of the present invention. Preferably the anuploid animal cell or modified anuploid animal cell is a porcine, murine, ovine, bovine, caprine or human cell.

In a further aspect of the present invention there is provided an animal embryo or transgenic animal embryo produced by the methods of the present invention. Preferably the animal embryo or transgenic animal embryo is a porcine, murine, ovine, bovine, caprine or human embryo.

In a still further aspect of the present invention there is provided an animal or transgenic animal produced by the methods of the present invention. Preferably the animal or transgenic animal is a porcine, murine, ovine, bovine, caprine or human animal.

The present invention will now be more fully described with reference to the accompanying Example. It should be understood, however, that the description following is illustrative only and should not be taken in any way as a restriction on the generality of the invention described above.

5

EXAMPLE**Efficiency of Nuclear Transfer and Nuclear Addition in Pigs**

Group	Oocytes	Fused (%)	Cleaved (%)	Blastocysts (%)
NT	97	44(45.4)	21(47.7)	6(13.6)
NA	112	54(48.2)	44(81.5)	17(31.5)
Following NT and NA a period of 6 hours was allowed prior to undertaking Activation/Fusion.				
NT: Nuclear transfer NA: Nuclear addition.				

Finally, it is to be understood that various alterations, modifications and/or additions may be made without departing from the spirit of the present invention as outlined herein.
